T

**See how this was done in two weeks time.....**

A variety of holes were cut in different location to help even de-watering and keep dry dock in balance during raising.

Cutting under water.

Now the water is being pumped out from the deck of the sunken dry dock. Air enters the compartments from above the water line to replace the weight of the water with air. Slowly buoyancy is being restored for the structure to rise.

Slowly the dry dock begins to rise.

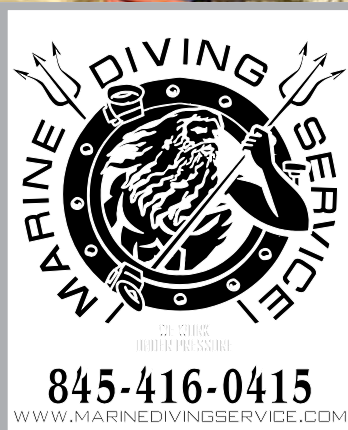

Large holes were cut in the deck to place the pumps. The the holes had hose pumps installed, and then sealed with rubber mats around the hoses using a underwater screw gun.

Airbags, hoses and pumps. It is another operation done from the back of the pickup truck.
